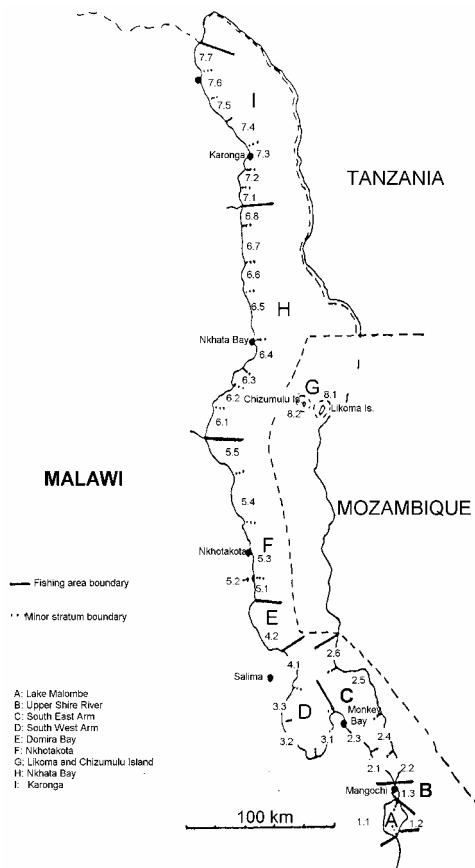

Figure 1. Map of statistical strata in Lake Malawi, the Upper Shire River and Lake Malombe.

Summary

There has been a general decline in the catches of the Domira bay fishery, from almost 3000 tons in the late 1970s to less than 500 t in the late 1990s. In the late 1970s and 1980s the other bigger species groups such as chambo and catfishes contributed significantly to the catches. However these species groups declined to very low levels by the 1990s and the fishery became dominated by utaka. The most important gear in the area is the chilimira net and ownership of this gear in the late 1990s appears stable at around 80 gears. The disappearance of the larger species groups and the declining trend in the catches from previous years indicates that the fishery may be overexploited.

Introduction

Domira Bay is situated on the western coast of Lake Malawi south of Nkotakota in stratum E (Figure 1). The bay is about 40 km wide and its shoreline consists of many reedy areas as well as marshes and lagoons. Mbenji Island, which is well known for its closed season to fishing, is situated in the middle of the Bay where chilimira fishing occurs. Domira Bay is relatively shallow, comprising of a wide shelf of shallow water. It has a 50 m contour of about 10 km offshore and a 100m contour 20 km out (Tweddle *et al*, 1994).

Catch statistics for the fisheries in Domira Bay have been collected since 1977 (Tweddle *et al*, 1994). The last published report on the Domira Bay fisheries was an analysis of catch and effort data for the period 1977-1989 (Tweddle *et al*, 1994). The purpose of this report is to update the catch and effort data available for Domira Bay up to the year 1999.

Methods of data collection

Statistical data on the traditional fisheries in all minor strata have been collected and analysed using Catch Assessment Survey (CAS) since 1976. The CAS was developed by Bazigos (1972) and implemented by Walker (1974; 1976). The CAS methods and the problems associated with it are documented elsewhere (Bazigos 1972, Walker 1974,1976, Alimoso 1988, Weyl & Manase 1999). The total catch and fishing effort in each area were estimated by combining data obtained in monthly CAS and data from the annual frame surveys. In this report the data are presented in gear and species group. Names of fishing gear used in this report are standard and the gear is described in Weyl *et al*. 2000.

Data analysis

Total catch

There were large fluctuations in the estimated total catch for Domira Bay (Figure 2). In the late 1970s to the early 1980s, the estimated catch ranged from between 1700 to nearly 3000 tons. In 1985 and 1986, the catch decreased to less than 1000 tons but it increased again to 2800 tons in 1989 where after the total catch declined to less than 500 tons in 1999.

The main contributors to the total catch were chilimira nets (59%), gillnets (28%) and kambuzi seines (10%). The ‘other gear’ group consisted of the longlines and mosquito nets. The contribution of the gill net has changed over time. Its greatest contribution to the total catch was in the early 1980s. By 1990s, chilimira net contributed the most (79%) to the total catch (1990 to 1999). The dominant species in the fishery were utaka (54%), kampango (14%), chambo (7%) and kambuzi (6%) (Figure 3).

Analysis by gear

Gear ownership

Temporal trends in the number of fishing gears is shown in Figure 4. In the chilimira fishery, there was a general increase in the 1980s, 90 nets were recorded in 1989. The numbers of chilimira gears in the area stabilised in the 1990s and in 1999, 79 chilimira nets were recorded at Domira Bay. During the 23 year period, the number of gill nets have fluctuated without showing any pattern, 329 gill nets were recorded in 1999. Similarly, the number of kambuzi seines have fluctuated, reaching a peak of 25 nets recorded in 1997. However in 1999, only 6 nets were recorded. Longline use has shown some fluctuations with a sudden peak in 1996 to 147 gears, however the numbers decreased reaching 43 longlines in 1999.

d) Longlines

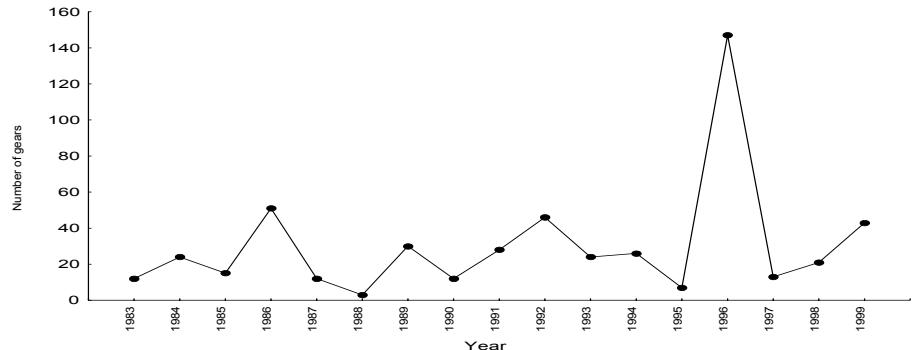

Figure 4. Temporal trends in the number of major fishing gear in Domira Bay 1983-1999.

Gillnets

Annual estimates for effort, CPUE and catch composition for the gill net fishery are shown in Figures 5, 6 and 7, respectively. Effort increased in the late 1980s but declined in the 1990s (Figure 5). Estimates of CPUE of the gill net fishery show an increase in the early 1980s but from 1983 there was a drastic decline till the 1990s (Figure 6). Total catch for the gill net fishery showed high catches from 1979 to 1983 averaging 1182 tons, after which catches started to decline to very low levels of less than 50 tons in the late 1990s (Figure 7).

Chambo, kampango and mlamba dominated the catch in the species composition of the gill net fishery (Figure 7). Chambo was a major component in the catch in the 1970s and 1980s. However, by the mid 1980s, chambo catches declined to 15 tons in 1991 after which the species was only a minor contributor to the total catch (Figure 7). In the 1990s, the catfishes dominated the catch composition of this fishery (Figure 7).

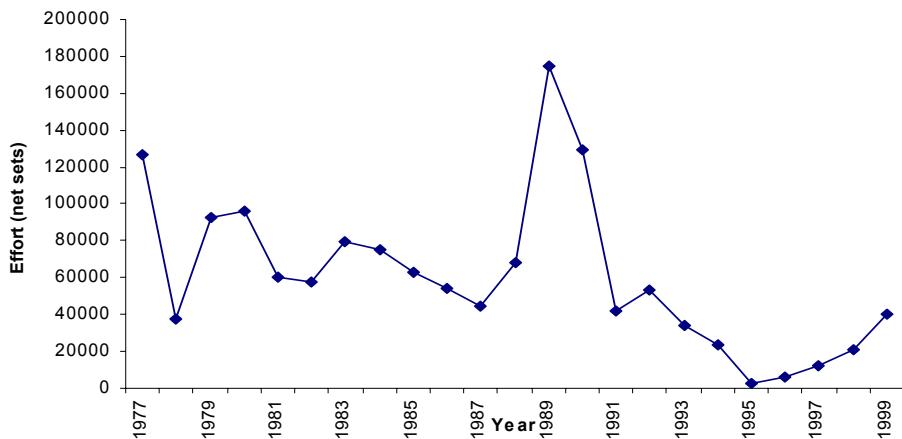

Figure 5. Gill net effort (91m gill net sets) in Domira bay from 1977 to 1999.

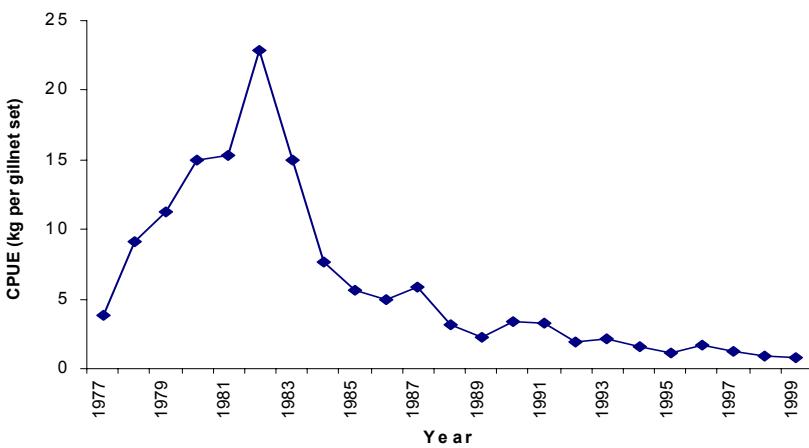

Figure 6. Gill net CPUE (kg per gill net set) in Domira Bay from 1977 to 1999.

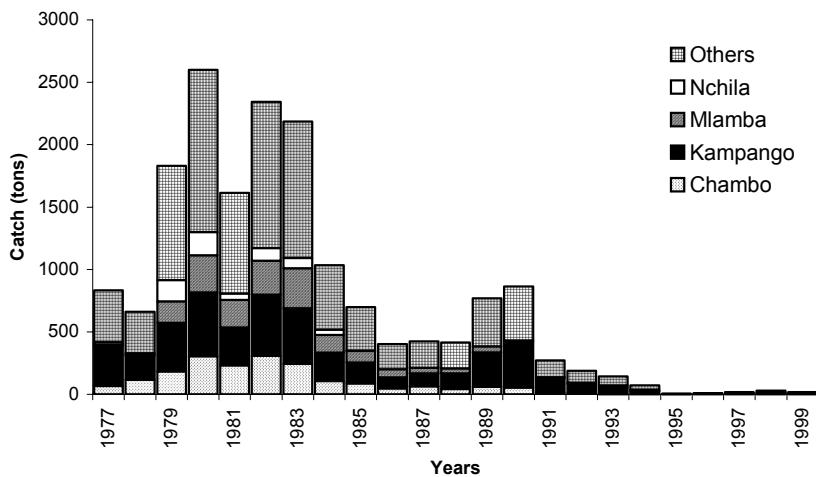

Figure 7. Total catch and species composition in the gill net fishery of Domira Bay from 1977 to 1999.

Chilimira nets

Annual estimates for effort, CPUE and catch composition for the chilimira fishery are shown in Figures 8, 9 and 10 respectively. Effort in this fishery fluctuated widely, however there was a general increase in effort in the late 1980s reaching very high levels in 1989 of 100 000 hauls (Note: this high Figure should be viewed with caution, Tweddle *et al* 1994). In the 1990s effort declined reaching over 32 000 hauls in 1999 (Figure 8). Estimates of the CPUE of the chilimira fishery also showed a fluctuating pattern with the highest CPUE (96 kg per haul) being recorded in 1981. From 1988 through to the 1990s, CPUE remained at less than 35 kg per haul (Figure 9). Total catch for the chilimira fishery was erratic, with some years yielding catches of more than 1700 tons (i.e. 1978, 1989 & 1994). Apart from the unusually high catch recorded in 1994, the 1990s yielded rather low catches averaging at 572 tons (Figure 10).

Utaka dominated the catch of the chilimira fishery throughout the 23 year period, comprising 90% of the catch for the whole period (Figure 10). Usipa was also recorded in some years in substantial amounts, the highest being 380 tons in 1997 (Figure 10).

Kambuzi seines

Annual estimates for effort, CPUE and catch composition for the kambuzi seine fishery are shown in Figures 11, 12 and 13 respectively. Effort throughout the 23-year period has fluctuated. Apart from unusual years when estimated effort was extremely high (1977 & 1989) the recorded effort for the rest of the years has not exceeded 11 000 hauls (Figure 11). Estimates of the CPUE of the kambuzi seine fishery also showed a fluctuating pattern (Figure 12). However there was a general decline in CPUE in the late 1990s to less than 20 kg per haul (Figure 12).

Total catch for the kambuzi fishery shows an unusually high catch estimate in 1977 followed by very low catches in the next proceeding years (Figure 13). In the late 1980s the catch started to increase reaching another high level in 1989 of 505 tons. In the 1990s there was a general decline in the catches to a very low level in 1999 of 15 tons (Figure 13). Kambuzi contributed 55% of the catches of the kambuzi seines during the 23 years. Usipa contributed 25% of the catches during the same period. Usipa started being recorded in substantial amounts in the late 1980s and 1990s, sometimes dominating the catch in some years (i.e. 1991 & 1993) (Figure 13).

Chambo was mainly recorded in the 1970s and 1980s catches and during the 23 years, it contributed only 7% of the catches. The ‘others’ group contributed in substantially in the 1970s and early 1980s catches altogether contributing 13% of the catches in the 23 years (Figure 14). This group consists of species groups such as utaka, kampango, other tilapia, nchila and mlamba.

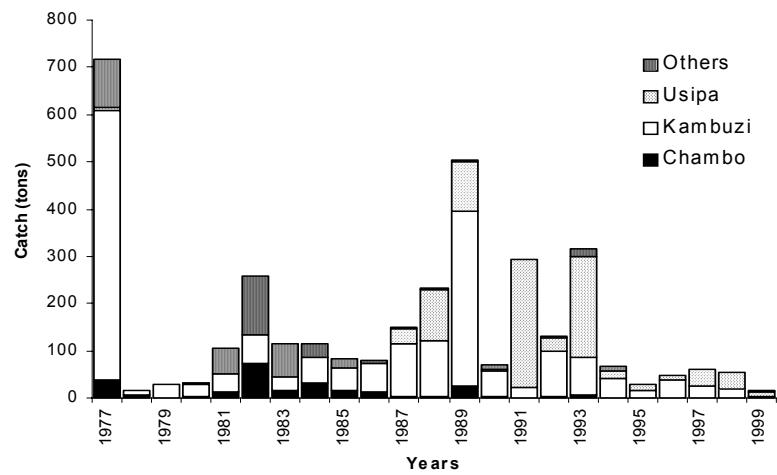

Figure 13. Total catch and species composition in the kambuzi seine fishery of Domira Bay from 1977 to 1999.

Analysis by species

Chambo

The main gear used for catching chambo in Domira Bay was the gill net which contributed 81% of the total chambo catch from 1977 to 1999 (Figure 14). There was a general increase in the chambo catches from the late 1970s to 1982 where 425 tons were recorded (Figure 14). In the late 1980s, there was a decline in the catches to very low levels in the 1990s, reaching less than 5 tons in the late 1990s (Figure 14). This decline in the catch is correlated to the decline in CPUE of the gill net fishery, which was the main fishery harvesting the chambo (Figure 15).

It is clear that the chambo stocks in Domira Bay have declined to very low levels in the late 1990s indicating that the stock has collapsed (Figure 14). Chambo contributed 7% of the total catch during the 23 years and it started to decline in the late 1980s at the same period when there were very high effort levels in the fishery. It is expected that chambo will continue to be caught at very low levels in this area.

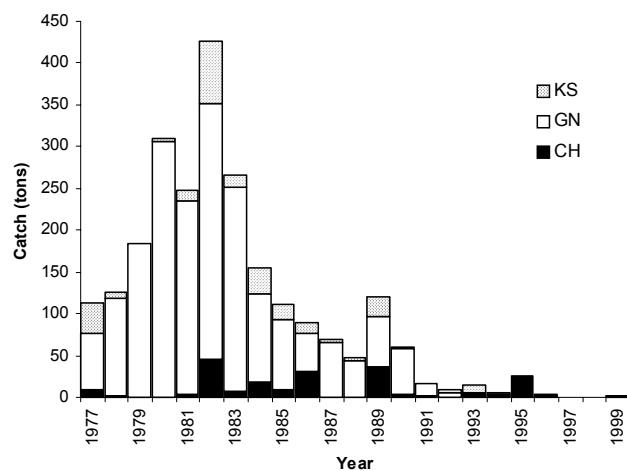

Figure 14. Total chambo catch by main contributing gear in Domira Bay from 1977 to 1999.

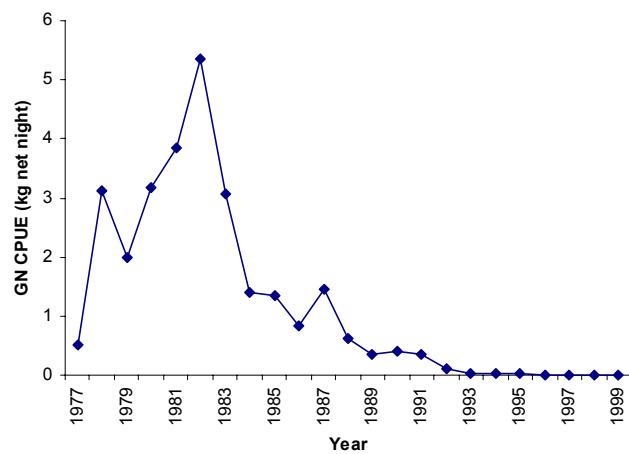

Figure 15. Chambo CPUE (kg net night) in the gill net fishery in Domira Bay for the period 1977 to 1999.

Utaka

The main harvesting gear for the utaka was the chilimira net, which contributed 99% of the total utaka catch for the 23-year period (Figure 16). The catches have fluctuated over the years with some very low catches recorded in the early 1980s as well as the late 1990s (average of 795 tons a year) (Figure 16). The high catches in the late 1980s are due to high effort levels in the chilimira fishery during this period. CPUE for the utaka in the chilimira fishery showed a general decline in the late 1980s, stabilising in the 1990s at low levels, averaging at 12 kg per haul (Figure 17).

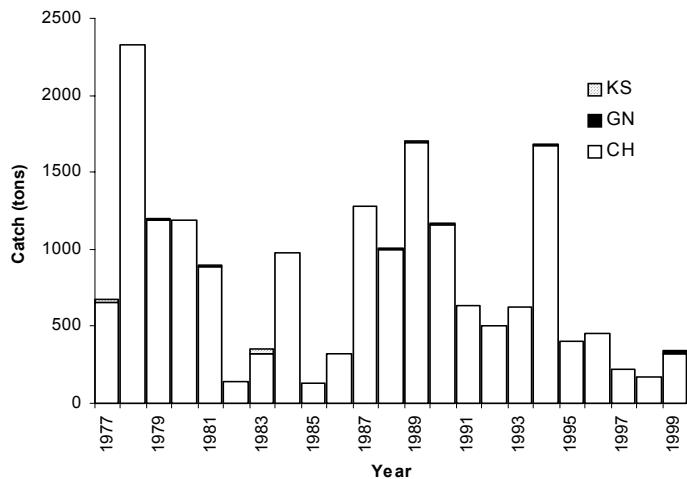

Figure 16. Total utaka catch by main contributing gear in Domira Bay from 1977 to 1999.

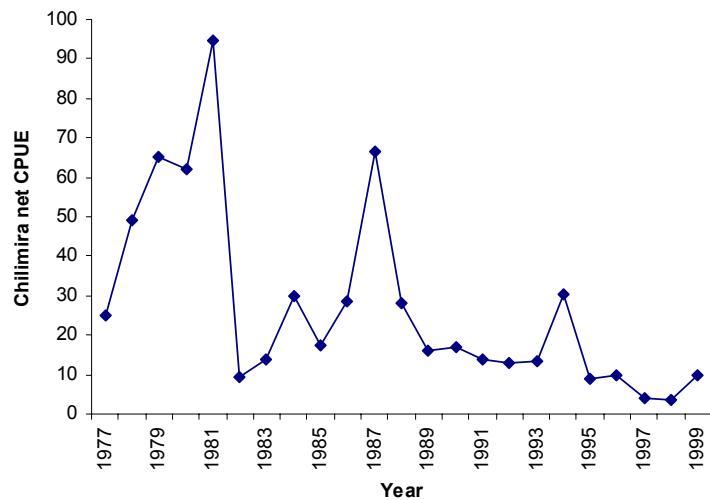

Figure 17. Utaka CPUE (kg per haul) in the chilimira fishery of Domira bay for the period 1977 to 1999.

Kampango

The main gear harvesting kampango was the gill net, which contributed 88% of the total kampango catch for all the years (Figure 19). High catches were recorded in the late 1970s to early 1980s. In the 1990s, there was a general decline of the catches to extremely low levels of less than 15 tons in the late 1990s (Figure 18). CPUE for the kampango in the gill net fishery was high in the early 1980s reaching its peak in 1984 at 8.5kg net night. However

CPUE started to decline in the late 1980s reaching very low levels in the late 1990s at less than 1kg net night (Figure 19).

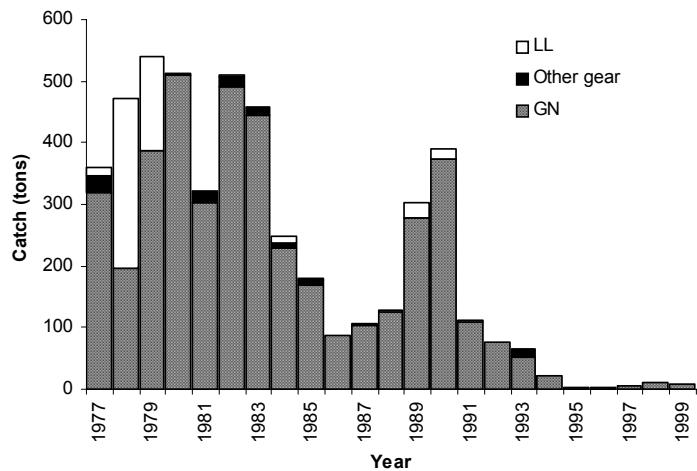

Figure 18. Total kampango catch by main contributing gear in Domira Bay from 1977 to 1999.

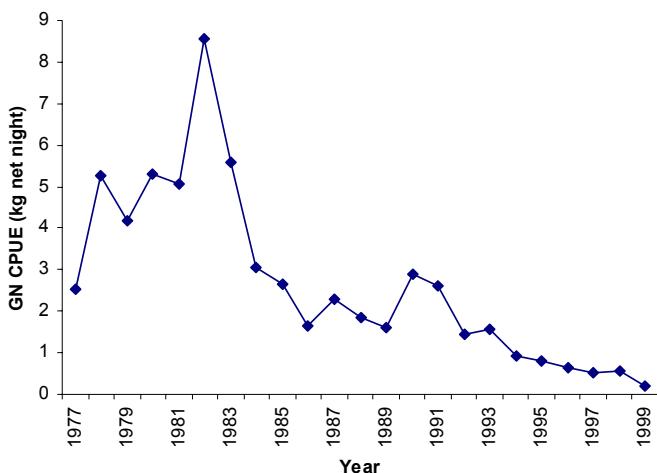

Figure 19. Kampango CPUE (kg net night) in the gill net fishery in Domira bay for the period 1977 to 1999.

Mlamba

88% of the total catch for the mlamba during the 23 year period was caught from gill nets and 6% from longlines. The data for the mlamba showed a similar trend to that of kampango, with very high catches in the early 1980s (reaching a peak of 337 tons). These high catches were followed by a steady decline in the late 1980s to less than 100 tons, eventually reaching less than 5 tons in the late 1990s. The CPUE of the mlamba group also showed a similar trend to the kampango with the highest CPUE in the early 1980s (with a peak of 5kg net night) and thereafter declining drastically to very low levels in the late 1990s of less than 1kg net night.

Discussion

Throughout the 23 year period, the Domira Bay fishery has been dominated by using chilimira nets targeting utaka. During the late 1990s, it is observed that there has been a decline in the overall catches in the fishery including chilimira net catches and the ownership of this gear shows that this fishery has stopped expanding. The gear ownership for the gill nets has not shown any negative trend towards the ownership of the gear despite the poor catches recorded for this gear especially in the late 1990s. The catches for the chambo and catfish groups have shown a drastic decline during the 23 year period correlating with the declining gill net catches in the area, since these species groups were mainly caught in the gill nets.

A declining trend can be observed in the overall catches in Domira bay, reaching very low levels in the late 1990s. As in Tweddle et al 1994, concern is also expressed concerning the absence of data from smaller gears (i.e. handlines and fishtraps) which are recorded in the annual frame surveys. This unrecorded data for the catches thus leads to an underestimation of the total catches in the area.

From the data, it can be recommended that there should be no further expansion of the chilimira fishery due to the fact that at present effort levels, the catches have reached extremely low levels. The chambo and catfish fisheries at the moment can be considered to have collapsed in this area. Reducing the number of gill nets operating in the area should be an option to consider in order to give the chambo and catfish stocks an opportunity to rebuild.

Acknowledgements

The authors would like to thank Salima District fisheries personnel for their hard work in collecting the data on which this report is based. In addition, thanks must go to the fishermen without whose cooperation this report would not have been possible. The production of this bulletin was facilitated by the GTZ supported National Aquatic Resource Management Programme.
